- Please do not open the exam before you are instructed to do so.
- Electronic devices are forbidden on your person, including cell phones, tablets, headphones, and laptops. Leave your cell phone off and in a bag; it should not be visible during the exam.
- The exam is closed book and closed notes except for your one-page 8.5×11 inch cheat sheet.
- You have 1 hour and 50 minutes (unless you are in the DSP program and have a larger time allowance).
- Please write your initials at the top right of each page after this one (e.g., write "JD" if you are John Doe). Finish this by the end of your 1 hour and 50 minutes.
- Mark your answers on the exam itself in the space provided. Do not attach any extra sheets.
- For multiple choice questions, fill in the bubble for the single best choice.
- For short and long answer questions, write within the boxes provided.
- The last question (Question 7) is for CS289A students only. Students enrolled in CS189 will not receive any credit for answering this question.

1 Multiple Choice

For the following questions, select the single best response. Each question is worth 1.5 points.

1. Assume a linear model $Y = Xw^* + z$, where $z \sim \mathcal{N}(0, I_n)$ and w^* is the true parameter we are trying to estimate. Consider the following objective:

$$\hat{w} = \operatorname{argmin}_{w \in \mathbb{R}^d} \|Xw - Y\|_2^2 + \lambda \|w\|_2^2 \qquad \lambda > 0 \tag{1}$$

How will increasing λ in Equation 1 affect the bias of the resulting estimator \hat{w} ?

- Bias will increase.
- Bias will decrease.
- \bigcirc Bias will remain unchanged.
- 2. How will increasing λ in Equation 1 affect the variance of the resulting estimator \hat{w} ?
 - Variance will increase.
 - \bigcirc Variance will decrease.
 - Variance will remain unchanged.
- 3. Consider the following probability density function:

Select the best description.

- \bigcirc X and Y appear to be both marginally and jointly Gaussian.
- \bigcirc *X* and *Y* appear to be marginally Gaussian but not jointly Gaussian.
- \bigcirc *X* and *Y* appear to be jointly Gaussian but not marginally Gaussian.

- For this question, X ∈ ℝ^{n×d} denotes an input data matrix of rank d, y ∈ ℝⁿ an outcome vector, w_{ridge} the ridge regression solution, and w_{OLS} the solution to unregularized linear regression. Select the false statement.
 - For all **X** and true linear predictors $\mathbf{w}^* \in \mathbb{R}^d$, under the statistical assumption $\mathbf{y} = \mathbf{X}\mathbf{w}^* + \mathbf{z}, \ \mathbf{z} \sim N(0, \sigma^2 I_n)$, we have $\operatorname{bias}(\mathbf{w}_{\operatorname{ridge}}) \geq \operatorname{bias}(\mathbf{w}_{\operatorname{OLS}})$, where the bias of an estimate $\hat{\mathbf{w}}$ of \mathbf{w}^* is defined as $\operatorname{bias}(\hat{\mathbf{w}}) = ||\mathbb{E}[\hat{\mathbf{w}}] - \mathbf{w}^*||_2$.
 - \bigcirc For all **X** and **y**, $||\mathbf{w}_{ridge}||_2 \le ||\mathbf{w}_{OLS}||_2$.
 - \bigcirc For all **X** and **y**, $\|\mathbf{w}_{ridge}\|_1 \leq \|\mathbf{w}_{OLS}\|_1$.
- 5. Suppose you have a dataset where the label is binary and generated by a fair coin toss and the input features are generated by sampling i.i.d. from a standard Gaussian, independently of the label. Let *n* denote the number of examples in your dataset and *d* the number of input features. You perform logistic regression using a random 70/30 train-validation split. Let Acc_{train} denote the training accuracy and Acc_{val} the validation accuracy. Select the **false** statement.
 - \bigcirc As $n \rightarrow \infty$, Acc_{train} approaches 50%.
 - \bigcirc As $n \rightarrow \infty$, Acc_{val} approaches 50%.
 - \bigcirc As $d \rightarrow \infty$, Acc_{train} approaches 100%.
 - \bigcirc As $d \rightarrow \infty$, Acc_{val} approaches 100%.
- 6. You are walking down Shattuck Ave. when you find a quarter on the ground. You see nothing unusual about this quarter, so you figure it is almost certainly a fair coin, though you realize that manufacturing irregularities in the coin minting process mean that coins are rarely *exactly* fair. You toss the coin 10 times and observe the following outcomes:

НННННННТ

with H denoting heads and T denoting tails. Assume coin tosses are independent. What is the maximum likelihood estimate of the next toss being heads?

- $\bigcirc \frac{5}{10}$ $\bigcirc \text{ between } \frac{5}{10} \text{ and } \frac{9}{10}$ $\bigcirc \frac{9}{10}$ $\bigcirc \text{ more than } \frac{9}{10}$
- 7. Consider the setup of the previous problem (Problem 6). What is the maximum a posteriori (MAP) estimate of the next toss being heads?
 - $\bigcirc \frac{5}{10}$ $\bigcirc \text{ between } \frac{5}{10} \text{ and } \frac{9}{10}$ $\bigcirc \frac{9}{10}$ $\bigcirc \text{ more than } \frac{9}{10}$

8. Consider a binary classification problem with two outcomes: positive and negative. The F_1 score of a classifier in such a problem is the harmonic mean between its precision and recall:

$$F_1 = 2\frac{p \cdot r}{p+r}.$$

Select the **true** statement relating a classifier's F_1 score on the test set to the bias and variance of its estimated parameters. You may assume the classifier is operating in the classical (non-interpolating) regime of bias and variance.

- \bigcirc Low bias implies a high F_1 score.
- \bigcirc Low variance implies a high F_1 score.
- \bigcirc A low F_1 score implies a high variance.
- \bigcirc A high F_1 score implies low bias.
- 9. Which of the following could depict the probability density function of a multivariate Gaussian with covariance matrix $\Sigma = \begin{bmatrix} \sigma_X^2 & \operatorname{cov}(X, Y) \\ \operatorname{cov}(Y, X) & \sigma_Y^2 \end{bmatrix} = \begin{bmatrix} 2.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix}$?

- 10. Julia is using SNE to visualize her high-dimensional dataset in two dimensions. She runs her code twice to find that it outputs different visualizations each time. Why is this expected? You may assume that Julia did not intentionally make her code deterministic by, for example, fixing the random seed.
 - This is expected due to the nonconvexity of the optimization objective, and also occurs with t-SNE.
 - This is expected due to the Gaussian distributions in SNE, and could be addressed by using t-SNE instead.
 - This is expected due to the iterative nature of SNE, and could be addressed by using PCA to find the solution to the SNE objective without gradient descent.

2 Short Answer

(2 points) Let X ∈ ℝ^{n×d} denote a mean-centered data matrix. with an SVD of X = UΣV[⊤], where the singular values are ordered in Σ left to right by size σ₁ ≥ σ₂ ≥ Write the rank-*k* PCA reconstruction of X. You may denote the submatrix consisting of the first *k* columns of a matrix M as M_k.

2. (2 points) Consider the following conditional distributions of *X*, a discrete random variable taking values in {0, 1, 2, 3, 4, 5}, given a binary label *Y*:

X	0	1	2	3	4	5
P(X Y=1)	0.1	0.1	0.1	0.2	0.2	0.3
P(X Y=0)	0.3	0.2	0.2	0.1	0.1	0.1

If the prior label probabilities are $P(Y = 0) = P(Y = 1) = \frac{1}{2}$, calculate the Bayes risk, i.e. the minimum probability of misclassification by a classifier taking *X* as input.

3. (2 points) Big Bird is training a five-layer neural network with ReLU activations to classify MNIST digits. His current network achieves a 90% validation accuracy. He wants to try different activation functions to try to improve his network. Will the validation accuracy increase or decrease when he replaces the ReLU function with the identity function? Justify your answer in a short sentence.

4. (2 points) Consider \mathbf{w}_{OLS} , the maximum likelihood estimate for \mathbf{w} in the model

$$\mathbf{y} = \mathbf{X}\mathbf{w} + \mathbf{z} \quad \mathbf{z} \sim \mathcal{N}(0, \sigma^2 I).$$

How does \mathbf{w}_{OLS} compare to the MAP estimate \mathbf{w}_{MAP} if you additionally assume a Gaussian prior $\mathcal{N}(0, \sigma^2 I)$ on w?

5. (2 points) Consider once again the MAP estimate \mathbf{w}_{MAP} under the model of the previous question and the same Gaussian prior $\mathcal{N}(0, \sigma^2 I)$. If the *i*th dimension of the estimate \mathbf{w}_{MAP} is equal to 0:

$$(\mathbf{w}_{\mathrm{MAP}})_i = 0,$$

what must be true of X and y? Assume that each feature of the data has mean 0 and that the data have been whitened such that $X^{T}X = nI$.

6. (2 points) In class and in your homework, you learned about the Rectified Linear Unit (ReLU) activation function. A related activation function is the Gaussian Error Linear Unit (GELU) activation function, defined as:

$$G(x) = x \mathbb{P}(X \le x) = x \int_{-\infty}^{x} p(z) d(z)$$

in which $X \sim \mathcal{N}(0, 1)$, $\mathbb{P}(X \le x)$ is the CDF of a standard Gaussian, and p(x) is the PDF of the standard Gaussian. Find the derivative of the GELU function $\frac{dG(x)}{dx}$ in terms of x, X, p, and \mathbb{P} .

7. (2 points) Consider a Gaussian covariance matrix $\Sigma \in \mathbb{R}^{2 \times 2}$ with the following eigenvectors:

$$\begin{bmatrix} \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} \end{bmatrix}$$
 with eigenvalue 4, and
$$\begin{bmatrix} \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} \end{bmatrix}$$
 with eigenvalue 2

Write Σ as a 2 \times 2 matrix.

8. (2 points) Consider a covariance matrix Σ with the same eigenvectors and eigenvalues as described in the previous question. Find the square root $\Sigma^{\frac{1}{2}}$ of Σ , once again simplifying to a 2×2 matrix.

9. (2 points) Gina is training a neural network with two hidden layers to classify MNIST digits. Each image has $28 \times 28 = 784$ features. The two hidden layers of the network both have 100 hidden units, and the output is one-dimensional. All layers (including the output) have a bias term. How many learnable parameters does the neural network have?

10. (2 points) Consider the following datapoints in \mathbb{R}^2 :

On the graph below, draw the two principal directions that PCA would return if run on the datapoints. Indicate which component explains more variance.

3 Fishing with a MAP

Oski is fishing for salmon. There are many types of fish in the great outdoors, so Oski is interested in the number of fish he must catch before finding a salmon. Oski realizes that he can model this as a geometric random variable

$$p(x \mid \theta) = (1 - \theta)^{x - 1} \theta,$$

in which θ is the underlying probability that a fish is a salmon, and x - 1 is the number of fish Oski catches before his first salmon.

(a) (2 points) Given a dataset of *n* trials $\mathcal{D} = \{x_1, x_2, \dots, x_n\}$, write down the log likelihood function log $p(\mathcal{D} \mid \theta)$. For the rest of this problem, you may assume that any stationary point of the log likelihood function is the global maximum.

(b) (1 point) Suppose Oski only has a single datapoint: $x_1 = 4$. What is the maximum likelihood estimate $\hat{\theta}_{MLE}$?

(c) (2 points) Now suppose that Oski has collected many salmon, and has many datapoints $\{x_i\}_{i=1}^n$. Write an expression for the maximum likelihood estimate, $\hat{\theta}_{MLE}$, as a function of the datapoints.

(d) (3 points) Oski realizes that a maximum likelihood estimate of θ might have been unreliable when he only had a single data point. He considers instead using maximum a posteriori (MAP) estimation by putting a prior $p(\theta)$ on θ . He settles on a Beta(α , β) distribution:

$$p(\theta) = \text{Beta}(\alpha, \beta) = \frac{1}{B(\alpha, \beta)} \theta^{\alpha - 1} (1 - \theta)^{\beta - 1},$$

in which α and β are constants and $B(\alpha, \beta)$ is a normalizing constant. Show that the posterior distribution over parameters $p(\theta \mid x)$ is Beta (γ, δ) , writing γ and δ in terms of α , β , θ and a single datapoint x. (Do not plug in x = 4 as in part (b).)

4 Neural Networks and Backpropagation

Abby is experimenting with a nonstandard neural network architecture, depicted below.

The input $x \in \mathbb{R}^d$ and output $\psi \in \mathbb{R}$ are enclosed in rectangles. The parameters are:

$$w_1, w_2, w_3 \in \mathbb{R}^d$$
 $w_4 \in \mathbb{R}$ $A \in \mathbb{R}^{d \times d}$

Computations are enclosed in circles. Intermediate activations are denoted as z_i and drawn on their corresponding edges. In this figure, $\sigma : \mathbb{R} \to \mathbb{R}$ is the sigmoid activation function and $f : \mathbb{R}^d \to \mathbb{R}^d$ denotes a function that subtracts the mean of a vector from itself:

$$\sigma(y) = \frac{1}{1 + e^{-y}} \qquad \qquad f(y) = y - \frac{1}{d} \sum_{i=1}^{d} (y)_i \mathbf{1}_d$$

in which $\mathbf{1}_d$ is the all-ones vector in \mathbb{R}^d and $(y)_i$ denotes the *i*th entry of *y*.

Abby now wants to train her network. In this problem, you will compute some of the derivatives needed to do so. Write all answers in terms of variables present in Figure 1.

(a) (2 points) $\frac{\partial \psi}{\partial w_1}$

initial here

(d) (3 points) $\frac{\partial \psi}{\partial w_3}$

5 Monitoring Regression

Kermit has found a bin of unused computer monitors lying around the EECS department. Many of the monitors are broken, but a few are still functional. Kermit decides to build a simple model to predict whether a given monitor will work. He encodes monitor *i* as a single feature $x_i \in \{-1, 1\}$ depending on its color. He also records whether monitor *i* is functional with a single indicator label $y_i \in \{0, 1\}$. Specifically,

$$x_i = \begin{cases} 1 & \text{if monitor } i \text{ is beige} \\ -1 & \text{otherwise} \end{cases} \qquad y_i = \begin{cases} 1 & \text{if monitor } i \text{ is functional} \\ 0 & \text{otherwise} \end{cases}$$

Kermit checks N monitors total and aggregates his findings into a dataset $X \in \{-1, 1\}^N$ with labels $Y \in \{0, 1\}^N$:

$$X = \begin{bmatrix} x_1 & x_2 & \cdots & x_n \end{bmatrix}^\top \qquad \qquad Y = \begin{bmatrix} y_1 & y_2 & \cdots & y_n \end{bmatrix}^\top$$

(a) (2 points) Let $n_{x,y}$ denote the number of monitors for which $x_i = x$ and $y_i = y$. For example, $n_{+1,0}$ denotes the number of non-functional beige monitors. Specifically:

$$n_{-1,0} = |\{i \mid x_i = -1 \text{ and } y_i = 0\}| \qquad n_{-1,1} = |\{i \mid x_i = -1 \text{ and } y_i = 1\}| \\ n_{+1,0} = |\{i \mid x_i = 1 \text{ and } y_i = 0\}| \qquad n_{+1,1} = |\{i \mid x_i = 1 \text{ and } y_i = 1\}|$$

Show that the solution to the linear regression objective

$$w_{\text{OLS}} = \operatorname{argmin}_{w \in \mathbb{R}} ||Xw - Y||_2^2$$

is given by

$$w_{\rm OLS} = \frac{n_{+1,1} - n_{-1,1}}{n}$$

(b) (3 points) Recall the logistic regression problem in one dimension:

$$\operatorname{argmin}_{w \in \mathbb{R}} f(w) = \operatorname{argmin}_{w \in \mathbb{R}} \left[-\sum_{i=1}^{n} y_i \log \left(\sigma(wx_i) \right) + (1 - y_i) \log \left(1 - \sigma(wx_i) \right) \right]$$

in which σ is the sigmoid function, $\sigma(z) = \frac{1}{1+e^{-z}}$. Show that

$$\frac{df(w)}{dw} = X^{\mathsf{T}}(\sigma(Xw) - Y)$$

in which $\sigma(Xw)$ denotes the result of applying σ elementwise to Xw.

initial here

(c) (4 points) Let

$$\hat{p} = \frac{n_{+1,1} + n_{-1,0}}{n}$$

Show that a solution to the logistic regression problem in the previous part is given by:

$$w = \log\left(\frac{\hat{p}}{1-\hat{p}}\right).$$

6 Classification with hedging

Consider a classification problem with *c* classes. The input is denoted as *x* and the label as $y \in \{1, 2, ..., c\}$. Suppose we allow our prediction to take one of 2c values:

$$1, 2, \ldots, c, 1_{\text{hedge}}, 2_{\text{hedge}}, \ldots, c_{\text{hedge}}$$

The i_{hedge} option represents a not-entirely-sure guess for class *i*. When one hedges one's bets by predicting i_{hedge} instead of *i*, the reward for being correct decreases, but the penalty for being wrong also decreases.

$$L(f(x), y) = \begin{cases} 1 & \text{if } f(x) \in \{1, 2, \dots, c\} \text{ and } f(x) \neq y \\ 0 & \text{if } f(x) \in \{1, 2, \dots, c\} \text{ and } f(x) = y \\ \lambda_e & \text{if } f(x) \in \{1_{\text{hedge}}, 2_{\text{hedge}}, \dots, c_{\text{hedge}}\} \text{ and } f(x) \neq y \\ \lambda_f & \text{if } f(x) \in \{1_{\text{hedge}}, 2_{\text{hedge}}, \dots, c_{\text{hedge}}\} \text{ and } f(x) = y \end{cases}$$

where $0 < \lambda_e, \lambda_f < 1$. The risk of a classifier *f* evaluated at input *x* is

$$R(f(x) \mid x) = \sum_{i=1}^{c} L(f(x), i) P(Y = i \mid x).$$

(a) (1 point) Let us assume that $\lambda_f < \lambda_e$. Explain why this is a reasonable assumption.

$$\underset{i \in \{1,2,\dots,c\}}{\operatorname{argmin}} R(i \mid x) \quad \text{and} \quad \underset{i \in \{1,2,\dots,c\}}{\operatorname{argmin}} R(i_{\text{hedge}} \mid x).$$

Express your answers as simple statements involving the conditional label probabilities $P(Y = i \mid x)$ for $i \in \{1, 2, ..., c\}$.

(c) (2 points) Given some $i \in \{1, 2, ..., c\}$, when is $R(i_{hedge} | x) \le R(i | x)$? Express your answer as an inequality in which the left hand side is P(Y = i | x) and the right hand side is an expression involving λ_e and λ_f .

(d) (1 point) Give an intuitive explanation for what happens when $\lambda_f = 0$.

(e) (2 points) Find a risk-minimizing predictor $f^*(x)$.

7 Visualizing high-dimensional data (CS289A only)

Only complete this problem if you are enrolled in CS289A. Do **not** complete this problem if you are enrolled in CS189.

In this problem, we will explore an approach for visualizing *N* high-dimensional datapoints $\{\mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_N\}, \mathbf{x}_i \in \mathbb{R}^d$ as two-dimensional embeddings $\{\mathbf{y}_1, \mathbf{y}_2, ..., \mathbf{y}_N\}, \mathbf{y}_i \in \mathbb{R}^2$.

(a) (2 points) Given a point \mathbf{x}_i , we would like to model a distribution over all other points \mathbf{x}_j $(i \neq j)$. The probability of sampling point \mathbf{x}_j should decrease as \mathbf{x}_j gets further away from \mathbf{x}_i , so we begin by defining a Gaussian distribution centered at each of the points \mathbf{x}_i :

$$\mathbb{P}(\mathbf{x} \mid \mathbf{x}_i) = \mathcal{N}(\mathbf{x} \mid \mathbf{x}_i, \boldsymbol{\Sigma}) = \frac{1}{(2\pi)^{\frac{d}{2}} |\boldsymbol{\Sigma}|^{\frac{1}{2}}} \exp\left\{-\frac{1}{2} \left(\mathbf{x} - \mathbf{x}_i\right)^{\mathsf{T}} \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \mathbf{x}_i)\right\}.$$

Let $\Sigma = \sigma^2 I_d$ for all such distributions. The probability of sampling point \mathbf{x}_j given point \mathbf{x}_i is then given by normalizing the probabilities under the Gaussian data-generating process:

$$\mathbf{p}_{ij} = \frac{\mathbb{P}(\mathbf{x}_j \mid \mathbf{x}_i)}{\sum_{k,k \neq i} \mathbb{P}(\mathbf{x}_k \mid \mathbf{x}_i)}$$

Show that p_{ij} can be expressed as,

$$\mathbf{p}_{ij} = \frac{\exp\left(-d_{ij}^2\right)}{\sum_{k,k\neq i} \exp\left(-d_{ik}^2\right)}$$

in which

$$d_{ij}^2 = \frac{\left\|\mathbf{x}_i - \mathbf{x}_j\right\|^2}{2\sigma^2}.$$

We now define an analogous conditional sampling distribution over the two-dimensional points \mathbf{y}_j . We will assume a covariance of $\Sigma = \frac{1}{2}I$ for the two-dimensional Gaussian distributions to simplify notation. Specifically, let the probability of sampling point \mathbf{y}_j given point \mathbf{y}_i be given by:

$$q_{ij} = \frac{E_{ij}}{Z_i}$$

in which

$$E_{ij} := \exp\left(-\hat{d}_{ij}^2\right) \qquad Z_i := \sum_{\substack{k \\ k \neq i}} \exp\left(-\hat{d}_{ik}^2\right) \qquad \hat{d}_{ij}^2 = \left\|\mathbf{y}_i - \mathbf{y}_j\right\|^2$$

E and *Z* are often referred to as the energy and partition functions in machine learning.

(b) (2 points) The Kullback-Leibler (KL) divergence, $D_{KL}(P \parallel Q)$, is a popular statistical distance to measure the difference between two distributions *P* and *Q*. KL divergence is given by

$$D_{\mathrm{KL}}(\mathbf{p}_i \parallel \mathbf{q}_i) \coloneqq \sum_i \mathbf{p}_{ij} \log \frac{\mathbf{p}_{ij}}{\mathbf{q}_{ij}}$$

Show that KL divergence penalizes a mismatch of a large p_{ij} with a small q_{ij} more severely than a mismatch of small p_{ij} with a large q_{ij} . For simplicity and in this part only, consider only a single term in the sum without trying to reason over the entire sum. Explain in a few words why this is a desirable property of a loss function that aims to model the local structure in data.

Define the cost of overall mapping to be the sum of KL divergences over the data,

$$C = \sum_{i} D_{\mathrm{KL}}(\mathbf{p}_{i} || \mathbf{q}_{i}) = \sum_{i} \sum_{\substack{j \\ j \neq i}} p_{ij} \log p_{ij} - \sum_{i} \sum_{\substack{j \\ j \neq i}} p_{ij} \log E_{ij} + \sum_{i} \sum_{\substack{j \\ j \neq i}} p_{ij} \log Z_{i}$$

We would like to optimize this cost function with respect to the two-dimensional embeddings \mathbf{y}_k (everything else is fixed) with a gradient based optimization procedure like SGD.

(c) (0.5 points) First show that,

$$\frac{\partial \log E_{kj}}{\partial \mathbf{y}_k} = 2(\mathbf{y}_j - \mathbf{y}_k)$$

(d) (0.5 points) Now show that,

$$\frac{\partial Z_i}{\partial \mathbf{y}_k} = \begin{cases} \frac{\partial E_{ik}}{\partial \mathbf{y}_k} & \text{if } i \neq k \\ \sum_{j, j \neq k} \frac{\partial E_{kj}}{\partial \mathbf{y}_k} & \text{if } i = k \end{cases}$$

(e) (3.0 points) Finally show that,

$$\frac{\partial C}{\partial \mathbf{y}_k} = 2 \sum_j \left(\mathbf{y}_k - \mathbf{y}_j \right) \left(p_{kj} - q_{kj} + p_{jk} - q_{jk} \right)$$

(f) (2.0 points) Find the Big $O(\cdot)$ time complexity of an efficient implementation of one step of gradient descent on the data embeddings $\{\mathbf{y}_i\}_{i=1}^N$. Write the complexity in terms of the number of datapoints *N* and their dimensionality *d*.
